What is the evidence base for this information?

This publication includes advice from consensus panels, the British Association of Urological Surgeons, the Department of Health and evidence-based sources. It is, therefore, a reflection of best urological practice in the UK. It is intended to supplement any advice you may already have been given by your GP or other healthcare professionals. Alternative treatments are outlined below and can be discussed in more detail with your Urologist or Specialist Nurse.

What does the procedure involve?

Instillation of BCG into the bladder for aggressive or recurrent superficial cancer of the bladder.

What are the benefits of the procedure?

To treat bladder cancer, helping to discourage re-growth and/or changes to bladder cancer.

What are the alternatives to this procedure?

Repeated cystoscopy, radiotherapy, surgical removal of the bladder with urinary diversion or bladder reconstruction, systemic chemotherapy.
What should I expect before the procedure?

Your Consultant Urologist has referred you for treatment of your superficial bladder cancer. Superficial bladder cancer affects the inner surface of the bladder only but has the ability to recur frequently and progress to more aggressive disease with invasion of the muscular layers of the bladder wall.

The aim of the treatment is to stop or slow down recurrence by instilling a drug in liquid form into the bladder. This is called intravesical immunotherapy. The drug treatment recommended for you is BCG. BCG is a commonly-used vaccine against tuberculosis (TB) and contains a bacterium from the same family as the TB bacterium which has been altered (attenuated) to reduce the risk of infection whilst retaining the ability to produce the immune reaction needed for its beneficial effect. It has been shown that putting liquid containing BCG vaccine into the bladder is an effective treatment for superficial bladder cancer.

Like all powerful treatments, it comes with some possible side-effects listed in this leaflet and the risk of these should be considered against the benefits of the treatment.
There is also some evidence that BCG treatment can interact with influenza vaccine. For this reason, it is recommended that you do not undergo vaccination against influenza for a six week period either side of your BCG instillation treatment.

There is also some evidence that the BCG treatment may interact with other vaccines. Therefore, please discuss any recent, or proposed, vaccinations with your Urology specialist nurse prior to commencing treatment.

The initial course is called the “Induction Course” and lasts for six weeks. One treatment is given each week for six consecutive weeks. Following completion of this, you will enter a program of treatment (called the “maintenance therapy”) that lasts up to three years. Maintenance therapy usually consists of periodic three week courses of treatment. Bladder inspections (cystoscopies) are performed between blocks of BCG therapy to assess the response, or effectiveness, of the treatment.

The main reasons for patients failing to complete the full course are side-effects (see below) and/or disease progression or recurrence.

You should limit your fluid input for six hours before each treatment and for two hours after the treatment being instilled.
On arrival in the clinic, you will be asked to pass urine, which will be tested to ensure that you do not have a urine infection. If you do, your treatment may need to be postponed for one week while you are treated with antibiotics.

Your treatment will not be able to go ahead if you are passing blood that you can see in your urine. Therefore, if this happens please ensure you tell the nurses prior to your treatment.

Your first treatment will take up to three hours and, depending on how well you tolerate the first treatment, future visits will take approximately 30 minutes.
Please be sure to inform your surgeon or specialist nurse in advance of your treatment if you have any of the following:

- an artificial heart valve
- a coronary artery stent
- a heart pacemaker or defibrillator
- an artificial joint
- an artificial blood vessel graft
- a neurosurgical shunt
- any other implanted foreign body
- a regular prescription for Warfarin, Clopidogrel (Plavix®), Apixaban, Ticagrelor or other blood-thinning drugs
- a previous or current MRSA infection
- a high risk of variant-CJD (if you have received a corneal transplant, a neurosurgical dural transplant or previous injections of human-derived growth hormone)

At some stage during the admission process, you will be asked to sign the consent form (reference FYCON100-1 Course of BCG) giving permission for your treatment to go ahead. This shows that you understand what is to be done and confirming that you wish to proceed. Make sure that you are given the opportunity to discuss any concerns and to ask any questions you may still have before signing the form. The form will be kept in your Patient Notes and you will also be offered a copy for your own records.
What happens during the procedure?

A fine plastic tube (called a catheter) will be passed into the bladder through your urethra (water pipe) and the medication (approximately half a cup of fluid) will be given through it. The catheter will then be removed. You will be asked not to pass urine for two hours to allow the medication to treat the bladder lining.

On your first visit, you will be asked to stay in the clinic for the duration of the treatment and to pass urine before you go home. For the remaining treatments, you may be allowed to go home with the medication in your bladder and pass urine after two hours when you are at home. However, you must ensure that you pass urine at your own home and do not use public toilets on the way home. This is because the drug can be harmful.
What happens immediately after the procedure?

In general terms, you should expect to be told how the procedure went and you should:

- ask if what was planned to be done was achieved
- let the medical staff know if you are in any discomfort
- ask what you can and cannot do
- feel free to ask any questions or discuss any concerns with the ward staff and members of the surgical team
- ensure that you are clear about what has been done and what is the next move
- once the treatment has been completed, you will be able to go home.

Urine passed within the first six hours after you have been treated should be disinfected by pouring a quantity of undiluted household bleach (equal to the amount of urine passed) into the toilet; this should then be left for 15 minutes before flushing the toilet.
You should drink plenty of fluids (two to three litres) for a few days after the treatment. Some patients find that, for a few days after BCG treatment, a glass of cranberry juice daily eases any bladder symptoms. Cranberry juice, however, should not be used if you are taking Warfarin.

Regular paracetamol can help to reduce any aches, pains or flu-like symptoms.
Are there any risks or side-effects?

Most procedures have a potential for side-effects. You should be reassured that, although all these complications are well-recognised, the majority of patients do not suffer any problems after a urological procedure.

**Frequent (greater than 1 in 10):**
- urinary tract infection requiring antibiotic treatment and postponement of the next dose of BCG
- some bladder discomfort after treatment
- flu-like symptoms which can persist for two to three days
- frequency and urgency of urination which can persist for two to three days
- failure to complete the course of treatment due to bladder discomfort
- blood and debris in the urine

**Common (between 1 in 10 and 1 in 100):**
- anaemia
- abdominal pain, nausea, vomiting and diarrhoea
- muscle and joint pain
- elevated temperature
- urinary incontinence
- inflammation of lung tissue
- persistent or severe bladder pain after treatment, sometimes requiring removal of the bladder
Uncommon (between 1 in 100 and 1 in 1000):
- changes in blood results
- inflammation of the liver
- skin rashes
- stricture of the urethra (water pipe) following repeated use of a catheter
- reduction in bladder capacity
- difficulty passing urine
- elevated levels of white cells in the urine
- BCGosis (generalised and potentially serious infection with the BCG bacteria requiring treatment in hospital with antibiotics)

Rare (between 1 in 1000 in 1 in 10,000):
- cough
- inflammation of the epididymis (tubes around the testicles)
Very rare (less than 1 in 10,000):

- reduction in appetite
- enlarged lymph nodes
- a number of inflammatory reactions which can affect various parts of the body (the liver, joints and the back of the eye)
- lowered blood pressure
- difficulty breathing
- back pain
- acute kidney failure
- chest pain
- dizziness
- increased sleepiness
- headache
- changes in sensation and nerve conduction
- confusion
- reduction in growth of hair

Hospital-acquired infection

- Colonisation with MRSA (0.9% - 1 in 110)
- Clostridium difficile bowel infection (0.2% - 1 in 500)
- MRSA bloodstream infection (0.08% - 1 in 1250)

The rates for hospital-acquired infection may be greater in high-risk patients e.g. with long-term drainage tubes, after removal of the bladder for cancer, after previous infections, after prolonged hospitalisation or after multiple admissions.
What should I expect when I get home?

By the time of your discharge from hospital, you should:

- be given advice about your recovery at home
- know when to resume normal activities such as work, exercise, driving, housework and sexual intimacy
- have been given a contact number if you have any concerns once you return home
- ask when your follow-up will be and who will arrange this (the hospital or your GP)

If you think you have a urine infection (i.e. pain on passing urine, frequency or foul-smelling urine) or if you develop a high temperature with backache, it is important to contact your GP and get treatment with antibiotics.

What else should I look out for?

Because this treatment is put directly into the bladder and not into the blood stream, you will not experience the side-effects often associated with other cancer drug treatments.
Are there any other important points?

You should wash your hands and genitals after you have passed urine and it is advisable to bring a wash bag with you to hospital when you come for the treatment.

Men should pass urine sitting down on the first occasion after the instillation but, thereafter, may pass urine in the normal fashion (standing).

You are advised not to have sexual intercourse for at least 24 hours after each treatment as this can cause some discomfort. For the duration of the treatment course, and for one week after the course, you should use a condom during sexual intercourse.

If you are a smoker, you should be aware that smoking seems to encourage recurrence of bladder cancer.
Driving after your treatment

It is your responsibility to ensure that you are fit to drive following your treatment. You do not normally need to notify the DVLA unless you have a medical condition that will last for longer than three months after your treatment and may affect your ability to drive. You should, however, check with your insurance company before returning to driving. Your doctors will be happy to provide you with advice on request.

Is there any research being carried out in this area?

Before your operation, your surgeon or Specialist Nurse will inform you about any relevant research studies taking place.

All surgical procedures, even those not currently the subject of active research, are subjected to rigorous clinical audit so that we can analyse our results and compare them with those of other surgeons. In this way, we can learn how to improve our techniques and our results; this means that our patients will get the best treatment available.
Frequently asked questions

Can I continue to work while receiving treatment?
You should take the remainder of the day off work after each treatment. This is because of the precautions needed for disposing of your urine. If you feel well enough you may return to work the next day. However if you experience any of the side effects mentioned earlier please take things easy and rest.

Can I drink alcohol during my course of treatment?
It is not known whether drinking alcohol has any effect on BCG. However it is recommended that you drink only one bottle of beer or one glass of wine a day whilst having treatment.

Can I have sex during my course of treatment?
Yes. Men should wear condoms during sex whilst they are receiving a course treatment and for one week following their final treatment. This is to avoid infecting their partners with BCG.

Women undergoing treatment should avoid having sex the night of their treatment. They need to ensure that the area has been thoroughly washed to remove any traces of BCG.

Women should use an effective contraception for the whole duration of their treatment to avoid pregnancy.
Can I breastfeed my baby while I am receiving a course of BCG treatment?

No. Breastfeeding is not recommended while you are receiving a course BCG treatment.

What will happen if I have a urine infection?

Each week when you come for your treatment the nurse will test a sample of your urine. If it shows signs of an infection you may not be able have your treatment that week. The nurse will arrange for you to have a course of antibiotics and will send a sample of your urine to the laboratory for testing.

You will return to hospital the following week for your treatment. The nurse will make you another appointment for you to replace for the one that you missed. This is to ensure that you receive the complete course of BCG.
Can I have my yearly flu jab while I am having my bladder treatment?

It is recommended that you do not have your flu jab during the six weeks before your bladder treatment or in the six weeks following your last bladder treatment.

What happens when my course of treatments are finished?

Following your final treatment you will receive an appointment for a bladder examination called a cystoscopy. This will be usually six to eight weeks after your last BCG treatment. The cystoscopy allows the Consultant to monitor your bladder cancer.
Special instructions for patients with indwelling catheters

When you come for your treatment the nurse will take a sample of urine from your catheter. If your urine is clear the drug will be placed into your bladder via your catheter. The catheter will then be clamped or a small bung (called a spigot) placed in the catheter to prevent the drug from draining out.

You must stay with us for the full two hours each time you come for your treatment.

When the drug has been in your bladder for the required time the nurse will release the clamp or spigot. This is to allow the drug to drain into your catheter bag.

After a short while, when the nurse is sure that all the drug has drained from your bladder, they will remove your catheter bag and replace it with a new one. At home for the following six hours any urine from your catheter needs to be disinfected using the following instructions.

Wear the gloves, which we will have given you. Put two bleach tablets or a cup of undiluted bleach into the toilet. Empty your catheter contents into the toilet and leave it for 15 minutes before flushing.
You will need to apply a new catheter bag in the morning. Again using gloves the used bag should be placed in the yellow container that we will supply you with. If you are unsure about changing your catheter bag we can arrange for a district nurse to do this for you.

We will give instructions for disposal of the yellow container before you leave on the day of your treatment.

Always wash your hands before and after handling your catheter.
Our Values: Caring about what we do • Respecting and valuing each other
